# CISSP Process Guide V.21

I'm Fadi Sodah (aka madunix), and I'm an IT Director. I've been in the IT realm for over twenty-six years and have held a variety of positions. I worked as a networks engineer, systems engineer and security engineer and I was among the Top 100 Hall of Fame HackTheBox. I'm an active member of Experts-Exchange (EE) since 2004. I have been awarded the Most Valuable Expert (EE MVE) in 2019. You can find me on Experts-Exchange (EE), LinkedIn, Facebook, Telegram, Discord and Twitter @madunix. I hold certifications in many areas of the IT field such as networking, systems, audit, IoT, AI and security: PCCSA, PCNSA, PCNSE, CCNP, CCIP, CISA, CISSP, CFR, CSC, ACE, CIOTSP, CAIP, CISM, eJPT, CyberSafe, SCSC, KCSP, KCTP, OCIF, OADCS, ADCI and ICATE.

To benefit others with the knowledge and experienced I gained during my study term, I have summarized the main underlying concepts in a general overview. I am hoping this consolidation of core concepts and processes would benefit those interested in becoming security experts.

This document intends to be supplementary, not a replacement for officially published study guides and books. I may have added multiple definitions of the same process or procedure due to the varying definitions from different resources such as the Official CBK, Sybex, NIST publications, SANS papers, or the AIO Shon Harris books. If you encounter any conflicts, please refer to the latest Official books CISSP CBK, AIO and Sybex. Being a CISSP candidate, you should fully understand CISSP concepts, methodologies and their implementations within the organization.

The CISSP exam is designed to test your presence of mind, knowledge, experience, concept and hardworking.

- Use Sybex as a baseline for your study
- In case of misconception keep referring to CBK CISSP book and index
- Review the notes from Sunflower powered by Nick Gill
- Review CISSP Process Guide powered by madunix
- Review Memory Palace CISSP Notes powered by Prashant
- If you study by yourself, you will always see your material from the same perspective; I recommend to choose a study group telegram and discord.
- Review NIST publication
- Check CISSP references <u>www.isc2.org/Certifications/References</u>
- Measure your progress through quizzes and practice exams, be aware don't go by the score try to fill your gaps
- Keep checking the (ESG) Elite Security Groups
  - https://thorteaches.com/cissp/
  - https://www.studynotesandtheory.com/
  - https://wentzwu.com/
  - https://prabhnair.in/
  - https://www.experts-exchange.com/members/madunix

Do not try any shortcut when it comes to reading books and gaining knowledge. This quick reference should be utilized as a fast recap of security concepts. It's essential that you read Official CISSP books first and then use these notes to get a recap of what you have learned. I wish you good luck for the CISSP exam.

You can send me a donation to my account to keep this document updated: paypal.me/FadiSodah Email:madunix@gmail.com

CISSP is registered certification marks of (ISC)<sup>2</sup>, Inc. Discalamer: Fadi Sodah is not affiliated with or endorsed by (ISC)<sup>2</sup>

Corporate Governance:	The importance of following Infosec standards:

User Provisioning	mandated. In some cases, a standard might become obsolete, and
<ul> <li>Monitoring and Enforcement</li> </ul>	a new standard must be researched and presented to senior
Incident Response	leadership for approval for implementation.

# Access Control Review:

The following is a review of the basic concepts in access control. Identification:

- Subjects supplying identification information
- Username, user ID, account number
- Authentication:
- Verifying the identification information

• Passphrase, PIN value, thumbprint, smart card, one-time password

Authorization:

• Using the identity of the subject together with other criteria to make a determination of operations that a subject can carry out on objects

• "I know who you are, now what am I going to allow you to do?" Accountability:

• Audit logs and monitoring to track subject activities with objects

# Authorization approval procedure:

Formalized

• Approval by the direct manager, data owner, security professional

Access permissions follow the principle of least privilege

- Balance security with the need for access
- $\bullet$  Avoid allowing too much privilege Conflicts of interest
- Remove privilege when no longer needed

# Due Diligence vs. Due Care:

• Due Diligence: "Researching" -- Investigating and understanding risks

• Due Diligence: "Doing" all the necessary tasks required to maintain the due care

• Due Care: "Doing" -- Developing policies and procedures to address risk

• Due Care is to act responsibly

# Data Protection:

When you think about data protection, there are essentially 5 key trends to be aware of:

- As always, the ability to recover data in the event of a loss or corruption is critical to why business does back up. It is a must.
- Next is disaster recovery (DR). In much the same way as application or data recovery, in the event of a natural disaster, the ability to get the business up and running is paramount. Statistically, businesses that can't recover from a disaster within 72 hours go out of business, so having a plan is critical, no matter the size of the business.
- Business continuity is a superset of DR and having a business continuity plan would mean having a good DR plan. It is imperative that not only are applications protected, but users can access the data and applications in the event of a disaster.
- The ability to reuse existing data for other business purposes. With the latest talk about "data being the new oil" or "natural useable resource," companies that can take advantage of this data are more likely to be successful. Having the ability to spin up copies of this data quickly for other business uses such as DevOps, analytics, or reporting as well as supporting a good DR strategy has become a way to take further advantage of your backup solution.
- The latest entry to the list is cyber resiliency. While cyber resiliency has been important for a long time, it is now top of everyone's mind due to the most recent attacks and the statistics that talk about how cyber attacks cost businesses a lot of money. The ability to recover from one of these attacks is not as simple as just a data recovery, so new planning has to be part of how businesses protect their data.

activities.	

#### Secure the Development Environment: Perform Dynamic Analysis: • Keep development, testing, and production environments • Recognize benefits of, and uses for, dynamic code analysis: completely separated, and control access to them by network users • Analyze code functioning in real world scenarios, minimizing the and deployment scripts through different assignable roles. need to create artificial scenarios to find errors. • If possible, separate responsibilities and access to different Find certain types of vulnerabilities that static code analysis environments so only those who require access to a particular might not find, such as race conditions. environment have access. Validate findings in the static code analysis. • Protect development, testing, and production environments from • Recognize limitations of dynamic analysis: physical access. • May produce false negatives (not reporting problems that actually • Protect the computers that developers use for development. For exist) and false positives (reporting problems that don't actually exist). example, encrypt local storage, require developers to log out when walking away from their desk, and so forth. • May provide a false sense that all security problems have been Avoid using public code repositories. found. • Make sure your code repository is on a secure system that is • Require the code to run, so they can't identify issues in code that protected from unauthorized physical and network access. won't compile. • Store code backups only in a secure storage location. • Typically require more expertise than static code analysis to • Maintain secure logs of all code check-ins and check-outs. perform properly. • Monitor who accesses the repository, when, and from where. • Depend on scripts to automate tasks or users manually performing steps, so you can't guarantee full coverage of the • Audit code frequently to verify that no malicious functions or vulnerabilities are added into production. source code. • Provide developers with realistic sample data to use for Perform Automated Security Testing: programming and testing instead of actual data. Use automated testing to supplement, rather than replace, • When it is necessary to destroy any source code, sensitive data, manual testing and code review. assets, or backups, make sure they are destroyed securely. Follow • To support test-driven development (TDD), create security tests compliance requirements, if applicable. within your automated unit tests to ensure that security tests are Perform Code Analysis: continually performed during the development process. When you perform static or dynamic code analysis: • As much as possible, try to design tests to be repeatable across • Combine static and dynamic code analysis to reveal more projects to save time, provide consistency, and facilitate testing security defects than performing either type of code analysis alone. process improvements over time. Combine automated code analysis with static and dynamic code analysis to reveal even more security defects. **Perform Static Analysis:** • Recognize benefits of, and uses for, static code analysis: • Quick operation, functioning much faster than a manual (human) code reviewer. • Scalable, can be run frequently (at each daily build, for example). · Robotic consistency and rigor in checking for specific types of security problems. • Low cost to operate, typically at a much lower cost than using experienced security architects and reviewers (whose efforts can be reserved for analysis tasks that benefit from human insight and creativity). • Ability to quickly scan for a huge range of problems, drawing the developer's focus to potential problem areas. Recognize limitations of static analysis: • May produce false negatives (not reporting problems that actually exist) and false positives (reporting problems that don't actually exist). • Inability to identify certain kinds of security problems, such as authentication and access control problems and incorrect use of cryptography APIs. • Inability to identify some problems due to other data values or resources not represented in code, such as misconfiguration of the host platform. • Inability to analyze some code that would not be able to compile due to missing libraries, incomplete code, missing resources, and so forth.

• May provide a false sense that all security problems have been found.

	Security Compass - SD Elements

# Threat Modeling Process:

- Define general security objectives and scope
  - Know your assets/data (not just physical).
    - Collect data such as existing documentation, policy, framework, guideline, DB, users stories, errors Check the accuracy of the collected data.
  - Gather security requirements already defined for you via compliance, government regulations, and industry standards.
  - Identify how you can address security and implement security requirements from a regulatory/data privacy perspective.

# Decompose

- Know your organization connectivity models.
   Ensure that no elements have been forgotten by identifying sub-components, dependencies and interaction points.
- Identify assets an attacker might be interested in, who should be allowed to access each area, and how access is controlled.
- Break up your application/system into conceptual entry points, components, and boundaries where an attacker might interact with it.
- $_{\odot}$   $\,$  Mark all untrusted data inputs.
- Diagram how data flows through the application/system using data flow diagrams (DFDs). DFD will represent how data moves between processes, storage, and external systems/services.
- Identify and rank threats
  - List all threats categories as possible, e.g., reconnaissance, social engineering, systems hacking, web-based threats, malware, hijacking and impersonation, denial of service Mobilebased threats, cloud-based threats, etc.
  - Existing threats should be identified before controls are listed for each threat, but the ranking of those threats will determine which controls will be implemented. Ranking threats is a key because the likelihood or impact of a threat may be so low that performing a control is not worth the cost.
  - Think like an attacker. It is terrible to crash, but it is worse to have wrong information and not even know about it. Examine your application and identify where threats exist such as checking return codes, errors, level of access, data sharing and all input if possible.
  - Ensure security requirements flow into test cases.
  - Use root cause analysis.
  - Use methodology like STRIDE (Spoofing, Tampering, Repudiation, Information Disclosure, Denial of Service, and Escalation of Privileges) to help you identify and rank threats.
  - If you are using third-party components, libraries and services consider and include their own threat models.
- Counter each threat
  - Follow security design patterns to deal with specific types of threats.
  - Provide countermeasures for each threat you need to address.

- Establish ongoing monitoring to identify when new security issues arise over time.
- Test the mitigation, in case threats not mitigated become security bugs in your bug repository.

# Cyber Kill Chain:

- Reconnaissance
- WeaponizationDelivery
- Delivery
  Exploitation
- Installation
- Command and Control
- Actions on Objectives

# The Cyber Security Operational Life Cycle:

- DISCOVER: Identify and map every asset across any environment. From here you can
- baseline the current and desired operational state.
- ASSESS: With every change, automatically assess the current state against the baseline state

of the environment, including misconfigurations, vulnerabilities and other key indicators of security health, such as out of date antivirus or high risk users.

• ANALYZE: Add context to the asset's exposure to prioritize remediation based on the asset's business criticality and the severity of the vulnerability.

• FIX: Prioritize which exposures to fix first, if at all, and select the appropriate

remediation technique, whether it's a temporary security control or a complete fix.

- Data Exfiltration:
- Covert channels
- File sharing services

# TOCTOU:

A type of race condition called Time of Check to Time of Use because the problem arises when shared data is changed between the time when it is initially checked, and when it is used. Race conditions are often non-deterministic, meaning that you can't predict the outcome since it is based on timing. Race conditions are often hard to debug, since running in a debugger adds timing delays that change the outcome. Prevent race conditions by preventing multiple simultaneous requests (locking) or through a synchronization mechanism.

# Storage vs. Timing Channels:

Covert channels can also be thought of in terms of two different categories: storage and timing. A

covert storage channel includes one process writing to a storage location and another process

reading from that location. A covert timing channel includes one process altering system resource so that changes in response time can signal information to the recipient process. Some usage of covert channels combines both aspects of storage and timing.

Examples of covert channels include the following:	Audit Report:
• Transmitting data over a rarely used port that the firewall does	• Purpose
not block.	• Scope
• Concealing data in the headers of TCP/IP packets so as to evade	<ul> <li>Results discovered or revealed by the audit</li> </ul>
signature analysis by intrusion	<ul> <li>Problems, events, and conditions</li> </ul>
detection systems.	<ul> <li>Standards, criteria, and baselines</li> </ul>
• Breaking the data up into multiple packets to be sent at different	<ul> <li>Causes, reasons, impact, and effect</li> </ul>
times in order to evade	Recommended solutions and safeguards
signature analysis.	IT security audit is designed to find:
• Transmitting data over a shared resource that is not typically	Malfunctioning controls
used as a communication channel	Inadequate controls
(i.e., file system metadata).	Failure to meet target standards/guidelines
• Transmitting encrypted data that cannot be inspected as it leaves	
the network.	Software-Defined Everything (SDx):

Point-to-Point Tunneling Protocol (PPTP):	Data Center Site Infrastructure Tier Standard Topology:
Works in a client/server model	Four-tiered architecture, each progressively more secure, reliable,
<ul> <li>Extends and protects PPP connections</li> </ul>	and redundant:
Works at the data link layer	Tier 1: Basic data center site infrastructure (basic
<ul> <li>Transmits over IP networks only</li> </ul>	protection)
Layer 2 Tunneling Protocol (L2TP):	Tier 2: Redundant site infrastructure capacity components
Hybrid of L2F and PPTP	Tier 3: Concurrently maintainable site infrastructure
• Extends and protects PPP connections	<ul> <li>Tier 4: Fault-tolerant site infrastructure (life-dependent</li> </ul>
• Works at the data link layer	applications and services)
• Transmits over multiple types of networks, not just IP	
Combined with IPSec for security	Temperature and Humidity Guidelines:
IPSec:	American Society of Heating, Refrigeration, and Air Conditioning
Handles multiple VPN connections at the same time	Engineers (ASHRAE) Technical Committee 9.9 provides guidelines
<ul> <li>Provides secure authentication and encryption</li> </ul>	for data center temperature and humidity.
• Supports only IP networks	<ul> <li>Temperature: 64.4-80.6°F, 18-27°C (at equipment</li> </ul>
• Focuses on LAN-to-LAN communication rather than user-to-user	intake)
communication	• Humidity: 40% @ 41.9°F (5.5'C) to 60% @ 59°F (15°C)
Works at the network layer, and provides security on top of IP	
Transport Layer Security (TLS):	Common Criteria CC:
Works at the session layer and protects mainly web and e-mail	• PP - what the customer needs
• works at the session layer and protects mainly web and e-mail traffic	• ST - what Vendor provides
Granular access control and configuration are available	• TOE - The actual product
Easy deployment since TLS is already embedded into web	• EAL - Rating which provides Evaluation and Assurance
• Easy deployment since TES is already embedded into web	Note: The EAL is a measure of how thoroughly the security
Can only protect a small number of protocol types	features the product vendor claims the product offers have been
	tested and reviewed, and by whom. The EAL does not offer any
Drawbacks multilayer protocols:	true measure of how well those security features will work in a
Covert channels are allowed	production environment, whether those features are preferable to
• Filters can be bypassed	other features offered by competing products, or whether the
Logically imposed network segment boundaries can be	product is "good."
overstepped	EAL:
Benefits multilayer protocols:	• EAL1 - Functionally tested (lowest rating)
A wide range of protocols can be used	• EAL2 - Structurally tested
• Encryption	• EAL2 - Methodically tested and checked
Flexibility and resiliency	• EAL4 - Methodically designed, tested and reviewed (medium
MPLS feature:	rating)
Traffic engineering	• EAL5 - Semi-formally designed and tested
Better router performance	• EAL6 - Semi-formally verified, designed and tested
Built-in tunneling	• EAL7 - Formally verified, designed and tested (highest rating)
Two main MPLS routing protocols:	Before selecting a Security Monitoring Tool type:
Label Distribution Protocol (LDP) - No Traffic Engineering	• It should collect information from numerous sources.
Resource Reservation Protocol with Traffic Engineering (RSVP-TE)	• It should be able to inter-operate with other systems, such as a
Label Switched Path (LSP) MPLS Router Roles/Positions	help desk or change management program.
are:	• It should comply with all relevant laws and industry regulations.
• Label Edge Router (LER) or "Ingress Node" - The router that first	• It should offer scalable reporting so you get both a high-level and
encapsulates a packet inside an MPLS LSP; Also the router that	low-level perspective on your security
makes the initial path selection.	Security Information and Event Management (SIEM):
• Label Switching Router (LSR) or "Transit Node" - A router that	Correlation
only does MPLS switching in the middle of an LSP.	Compliance
• Egress Node - The final router at the end of an LSP, which	Alert
removes the label.	
Generic Routing Encapsulation (GRE) Tunnel	
Tunneling protocol developed by Cisco that can encapsulate a wide	
variety of network layer protocols inside virtual point-to-point links	
over an internet protocol network.	

What S	SIEMs Provide:	Tasks may be performed automatically for you with tools
•	Data aggregation: Bringing many logs from operating	such as SIEMs:
•	system, network devices, and applications together for	Filter out unnecessary or duplicate data
	analysis	Combine sources
•	Correlation: Looking for common attributes within the logs	Synchronize events logged in different sources
	that may be used to chain together events	Normalize data formats
•	Alerting	Store data securely
•	Dashboards: Much quicker than reading through reports	Data Collection, Analysis, and Correlation
•	Compliance: Can generate compliance reports based on	SIEM on Cloudthe benefits are:
	event log data	No capital expenditure
•	Retention: Long-term storage - Most SIEMs don't provide	No need to invest on premise machines
	long-term storage in an active manner. They tend to	No need to invest in technical support for hardware
	offload events after a certain age to an internal archival	No installation charges
	area. This is due to the fact that you could end up with	• Only fine tuning
	billions upon billions of events over time, and most	• Upgrades rolled out automatically by the cloud provider
	systems cannot manage that much data efficiently.	Security Mode:
•	Forensic analysis: Searching through logs from many	Dedicated security mode (All users can access all data).
	systems by specific date, time, or other criteria	<ul> <li>System high-security mode (on a need-to-know basis, all users</li> </ul>
		can access limited data).
		Compartmented security mode (on a need-to-know basis, all
		users can access limited data as per the formal access approval).
		Multilevel security mode (on a need-to-know basis, all users can
		access limited data as per formal access approval and clearance).
		Prevent SQL Injection (SQLi):
		Perform Input Validation
		Limit Account Privileges
		Use Stored Procedures
		In a SQL injection attack, an attacker could:
		Harvest and crack password hashes
		Delete and modify customer records
		Read and write system files
		Injection attacks:
	SQL injection attack consists of insertion or "injection" of a SQL	
	<ul><li>query via the input</li><li>HTML injection is a type of injection issue that occurs when a</li></ul>	
		user is able to control an input point and is able to inject arbitrary
		HTML code into a vulnerable web page
		<ul> <li>Command injection is an attack in which the goal is the execution</li> </ul>
		of arbitrary commands on the host operating system via a
	vulnerable application	
	• Code injection allows the attacker to add his own code that is	
	then executed by the application.	
	Web App Threats:	
		Cookie Poisoning
	Insecure Storage	
	Information Leakage	
	Directory Traversal	
	Parameter/Form Tampering	
	DOS Attack	
	Buffer Overflow	
	Log tampering	
	• SQL Injection	
		• Cross-Site (XSS)
		Cross-Site Request Forgery
		Security Misconfiguration
		Broken Session Management
		DMZ attack
		Session Hijacking
		Network Access Attacks

DNSSEC:	Social Engineering:
Adds security to DNS by enabling DNS responses to be validated.	It's important for any user to understand social engineering and
DNSSEC uses a process called zone signing that uses digital	their tactics. Additionally, by understanding the underlying
certificates to sign DNS records.	principles, it becomes easier to avoid being tricked by them. The
Threats to DNS:	following sections introduce these principles.
<ul> <li>Footprinting: An attacker attempts to gather all DNS</li> </ul>	Authority
records for a domain via domain transfer in order to map	Intimidation
out the target environment.	Consensus / Social Proof
<ul> <li>Denial of Service (DoS): Flooding of DNS servers can</li> </ul>	Scarcity
prevent the server from responding to DNS requests.	• Urgency
<ul> <li>Redirection: An attacker redirects queries to a server</li> </ul>	Familiarity/Liking
under the attacker's control.	• Trust
<ul> <li>Spoofing: Also known as DNS poisoning where the</li> </ul>	Wireless and RF Vulnerabilities:

#### **Provide Secure Communication in Web**

• Make sure the network is securely configured, but program as though network security will eventually be compromised.

• Use transport layer encryption (e.g., HTTPS, TLS, SSL) whenever possible—especially for communicating any sensitive data or session tokens to APIs and services.

• Protect data and requests transmitted between a client and server. For example, use parameterized queries to avoid Structured Query Language (SQL) injection.

• Do not send sensitive data over inappropriate channels, such SMS, MMS, or notification services.

• Account for outside entities (e.g., third-party analytics services, social networks) by using their SSL versions for routines run in the browser/webkit.

• Use strong, industry standard encryption algorithms with appropriate key lengths.

• Use certificates signed by a trusted CA provider, and use certificate pinning for security conscious applications.

• Require SSL chain verification, and establish a secure connection only after you verify the identity of the endpoint server using trusted certificates in the key chain.

• Fail safely, blocking communication and alerting the user if the application detects an invalid certificate.

• If practical, encrypt sensitive data before providing it to the SSL channel to provide an extra layer of defense in case the SSL/TLS layer is compromised.

# Mobile devices are prime vectors for data loss; areas the professional should focus on:

Secure communications

- Antimalware
- Strong authentication
- Passwords
- Control 3rd party software
- Separate secure mobile gateways
- Lockdown, audits
- Penetration tests
- Mobile security policy

# Basic Types of Mobile Threats:

• Denial of service Deny or degrade service to users. Jamming of wireless communications, overloading networks with bogus traffic, ransomware, theft of mobile devices or mobile services.

• Geolocation Physical tracking of users. Passively or actively obtaining accurate three-dimensional coordinates of target, possibly including speed and direction.

• Information disclosure Unauthorized access to information or services.

Interception of data in transit, leakage or exfiltration of users, app, or enterprise data, tracking of user location, eavesdropping on voice or data communications, surreptitiously activating the phone's microphone or camera to spy on the user.

• Spoofing Impersonating something or someone. Email or SMS message pretending to be from the boss or colleague (social engineering); a fraudulent Wi-Fi access point or cellular base station mimicking a legitimate one.

• Tampering Modifying data, software, firmware, or hardware without authorization. Modifying data in transit, inserting tampered hardware or software into the supply chain, repackaging legitimate apps with malware, modifying network or device configuration (e.g., jailbreaking or rooting a phone).

#### **Cybersecurity Framework:**

• Identify – Develop the organizational understanding to manage cybersecurity risk to systems, assets, data, and capabilities. The activities in the Identify Function are foundational for effective use of the Framework. Understanding the business context, the resources that support critical functions, and the related cybersecurity risks enables an organization to focus and prioritize its efforts, consistent with its risk management strategy and business needs. Examples of outcome Categories within this Function include: Asset Management; Business Environment; Governance; Risk Assessment; and Risk Management Strategy. • Protect - Develop and implement the appropriate safeguards to ensure delivery of critical infrastructure services. The Protect Function supports the ability to limit or contain the impact of a potential cybersecurity event. Examples of outcome Categories within this Function include: Access Control; Awareness and Training; Data Security; Information Protection Processes and Procedures; Maintenance; and Protective Technology. • Detect - Develop and implement the appropriate activities to

identify the occurrence of a cybersecurity event. The Detect Function enables timely discovery of cybersecurity events. Examples of outcome Categories within this Function include: Anomalies and Events; Security Continuous Monitoring; and Detection Processes.

• Respond – Develop and implement the appropriate activities to take action regarding a detected cybersecurity event. The Respond Function supports the ability to contain the impact of a potential cybersecurity event. Examples of outcome Categories within this Function include: Response Planning; Communications; Analysis; Mitigation; and Improvements.

• Recover – Develop and implement the appropriate activities to maintain plans for resilience and to restore any capabilities or services that were impaired due to a cybersecurity event. The Recover Function supports timely recovery to normal operations to reduce the impact from a cybersecurity event. Examples of outcome Categories within this Function include: Recovery Planning; Improvements; and Communications.

#### Attacks:

 Passive Attacks – hard to detect because the attacker is not affecting the protocol. Examples are Eavesdropping, network sniffing, and capturing data as it passes, used to gather data prior to an active attack.

• Active Attacks – Altering messages, modifying system files, and masquerading are examples because the attacker is actually doing something.

• Ciphertext Attacks - The attacker obtains ciphertext of several messages, with each message being encrypted using the same encryption algorithm. Attacker's goal is to discover the key. Most common attacks are easy to get ciphertext, but hardest attack to be successful at.

• Known-Plaintext Attack - The attacker has the ciphertext of several messages, but also the plaintext of those messages. The goal is to discover the key by reverse-engineering and trial/error attempts

• Chosen Plaintext Attack - The attacker not only has access to the ciphertext and associated plaintext for several messages, he also chooses the plaintext that gets encrypted. More powerful than a known-plaintext attack because the attacker can choose specific plaintext blocks to encrypt, ones that might yield more info about the key.

• Chosen-Ciphertext Attack: Attacker can choose different ciphertexts to be decrypted and has access to the decrypted plaintext. This is a harder attack to carry out, and the attacker would need to have control of the system that contains the cryptosystem

• Adaptive Attacks: Each of the attacks has a derivative with the word adaptive in front of it. This means that an attacker can carry out one of these attacks, and depend on what is gleaned from the first attack, the next attack can be modified. This is the process of reverse-engineering or cryptanalysis attacks.

• Birthday attack: a Cryptographic attack that exploits the math behind the birthday problem in the probability theory forces collisions within hashing functions.

• Brute force attacks: continually tries different inputs to achieve a predefined goal. Brute force is defined as "trying every possible combination until the correct one is identified".

• Buffer overflow: Too much data is put into the buffers that make up a stack. Common attacks vector are used by hackers to run malicious code on a target system.

• Cross-site scripting: refers to an attack where vulnerability is found on a website that allows an attacker to inject malicious code into a web application

• Dictionary attacks: Files of thousands of words are compared to the user's password until a match is found.

• DNS poisoning: Attacker makes a DNS server resolve a hostname into an incorrect IP address

• Fraggle attack: A DDoS attack type on a computer that floods the target system with a large amount of UDP echo traffic to IP broadcast addresses.

• Pharming: redirects a victim to a seemingly legitimate, yet fake, web site

• Phishing: type of social engineering with the goal of obtaining personal information, credentials, credit card number, or financial data. The attacker's lure, or fish, for sensitive data through various different methods

• Mail Bombing: This is an attack used to overwhelm mail servers and clients with unrequested e-mails. Using e-mail filtering and properly configuring email relay functionality on mail servers can be used to protect this attack.

• Ping of Death: A DoS attack type on a computer that involves sending malformed or oversized ICMP packets to a target.

• Replay attack: a form of network attack in which a valid data transmission is maliciously or fraudulently repeated with the goal of obtaining unauthorized access.

• Replay Attack: an attacker capturing the traffic from a legitimate session and replaying it to authenticate his session

• Session hijacking: If an attacker can correctly predict the TCP sequence numbers that the two systems will use, then she can create packets containing those numbers and fool the receiving system into thinking that the packets are coming from the authorized sending system. She can then take over the TCP connection between the two systems.

• Side-channel attacks: Nonintrusive and are used to uncover sensitive information about how a component works, without trying to compromise any type of flaw or Weakness. A noninvasive attack is one in which the attacker watches how something works and how it reacts to different situations instead of trying to "invade" it with more intrusive measures. side-channel attacks are fault generation, differential power analysis, electromagnetic analysis, timing, and software attacks.

• Smurf attack: A DDoS attack type on a computer that floods the target system with spoofed broadcast ICMP packets.

<ul> <li>Social engineering: An attacker falsely convinces an individual that she hask mencessary authorization to access specific resources.</li> <li>Spoofing at Login: an attacker can use a program that present trace conditions:</li> <li>Lock the shared resource when the process is modifying it, and unlock the when the process is done. Note that this approach can get unlock the when the process is done. Note that this approach can get unlock the when the process is done. Wireless Attack:	Common vulnerabilities and threats of Security
• Roque AP	Common vulnerabilities and threats of Security Architecture:
Kogue AP     Interference	
Jamming	<ul> <li>Poor memory management</li> <li>Covert channels (storage and timing)</li> </ul>
• Evil Twin	
• Evil Twill • War Driving	<ul> <li>Insufficient system redundancy</li> <li>Poor access control</li> </ul>
War Chalking	Hardware failure
• IV attack	Misuse of privileges
WEP/WPA attacks	Buffer overflows
Secure configuration of Hardware devices:	Memory attacks
Secure build	• DoS
Secure initial configuration	Reverse engineering
Host hardening - remove all non-needed	Hacking
Host Naturning - remove an non-needed     Host Patching	• Emanations
Host lockdown	State attacks (race conditions)
Secure ongoing configuration, maintenance	A honeypot can be used:
RFID Attacks:	Gathering threat intelligence
RFID Counterfeiting	Distracting attackers
RFID Counternating     RFID Sniffing	Delaying attackers
Tracking	Endpoint Protection:
Denial of Service	Built-in firewall functionality.
• Spoofing	<ul> <li>Intrusion detection system (IDS) /intrusion prevention system</li> </ul>
Repudiation	(IPS) functionality.
Insert Attacks	Data loss prevention (DLP) functionality.
Replay Attacks	Application whitelisting / blacklisting functionality.
Physical Attacks	• Full disk encryption.
Viruses	Management interfaces for configuration of each endpoint or
RFID attacks:	groups of endpoints.
Eavesdropping/Skimming	• A centralized in-house server for distributing malware signature
Traffic Analysis	updates.
• Spoofing	<b>Note:</b> A discovery tool is a primary component of a DLP solution.
Denial of Service Attack/Distributed Denial of Service Attack	This might be employed for purposes of identifying and collecting
RFID Reader Integrity	pertinent data.
Personal Privacy	DLP Architecture
Attacks on VLAN:	• Data in motion (DIM): Network-based or gateway DLP.
MAC Flooding Attack	Monitors SMTP, HTTP, HTTPS, SSH, FTP, etc., for sensitive
• 802.1Q and Inter-Switch Link Protocol (ISL) Tagging Attack	data and prevents it from leaving the organization.
Double-Encapsulated 802.1Q/Nested VLAN Attack	• Data at rest (DAR): Storage-based. Used for tracking and
ARP Attacks	identification data as it's installed on the system where
Multicast Brute Force Attack	the data resides. Generally needs another mechanism for
Spanning-Tree Attack	any enforcement.
Random Frame Stress Attack	<ul> <li>Data in use (DIU): Client- or endpoint-based. Resides on</li> </ul>
Methods of Cryptanalytic Attacks:	users' workstations. Requires great amount of
<ul> <li>Cipher text-Only Attack (Only Ciphertext)</li> </ul>	management. Not easy to deploy and manage.
Known Plaintext (Both Plaintext and Ciphertext available)	
• Chosen Plaintext (Known algorithm, Adaptive where Plaintext can	
be changed)	DLP Policy Considerations:
• Chosen Ciphertext (Known algorithm, Adaptive where Ciphertext	• What classification of data is permitted to be stored in the
can be changed)	cloud?
	Where can this data be stored (geographical locations)?
	How should this data be stored (encrypted)?
	What type of access controls need put in place?
	• Who, what, where, when, can data be accessed by or
	from?
	When can data leave the cloud, if ever?
	Block Storage:
	Primary role of storage is to group disks together into
	logical volumes ( LUNs, virtual disks, generic volume
	storage, and elastic block storage)
	None of these have a file system when created
	It's up to the OS on the VM to create the file system

#### **Object Storage:**

- Has a flat file system on it
- Provides for simple object storage (files of nearly any type)
- Objects are accessible via browser and REST API
- AWS refers to these as buckets in their S3 service
- Rackspace offers cloud files
- Object storage is typically the best way to store an OS (image)
- Data can be replicated across multiple object storage servers or sites
- Offer basic file usage, nothing fancy

# General types of viruses:

- File Infectors Infects program or object files.
- Boot sector infectors Attach or replace boot records
- $\bullet$  System Infectors Attaches to system files or system structure
- Companion virus Does not physically touch the target file
- Email Virus Aware of the email system.
- Multipartite Reproduces in more than one way
- $\bullet$  Macro Virus Uses macro programming of the app. Infect data files
- Script Virus Standalone files that can be executed by an interpreter
- Script host .vbs as host to script virus.

# RAID:

Some of the RAID protection options are:

• RAID0 - Striped

• RAID 1 withstands failure of one drive within one of the mirrored pairs. The number of required drives is twice the amount required to store data.

- RAID2 Hamming Code requires either 14 or 39 disks
- RAID3 Striped Set with Dedicated Parity (Byte Level)
- RAID4 Striped Set with Dedicated Parity (Block Level)

• RAID 5 protection is also available. Data blocks are striped horizontally across the members of a RAID 5 group, and each member owns some data tracks and some parity tracks.

- RAID 6 protects data with failures of up to 2 drives per RAID group.
- RAID1+0 striped set of mirrored disks

# Power:

- Blackout: Generator
- Brownout: (UPS) Uninterruptible Power Supply
- Surge: Surge protector
- Spike: Surge protector
- Noise: Power conditioner
- Clean power: No solution is needed

# Hashing:

- MDS Message-Digest Algorithm 128-bit digest
- SHA 160-bit digest
- HAVAL
- RIPEMD-160
- Birthday attacks possible

# Symmetric Algorithms:

- Data Encryption Standard (DES)
- 3DES (Triple DES)
- Blowfish
- Twofish
- International Data Encryption Algorithm (IDEA)
- RC4, RCS, and RCG
- Advanced Encryption Standard (AES)
- Secure and Fast Encryption Routine (SAFER)
- Serpent
- CAST

# Asymmetric Algorithms:

- RSA factoring the product of two large prime numbers
- Diffie-Hellmann Algorithm
- EI Gamal- discrete logs
- Elliptic Curve Cryptography (ECC)

Encryption:	
• Use encryption that is strong enough to protect the data.	Masking and Obfuscation:
• But the stronger encryption is, the longer it will take to decrypt.	Data obfuscation is the process of changing data so it
Whatever encryption you use, it shouldn't slow down	doesn't appear to be what it is.
performance unacceptably for most of your users.	Generally used to comply with standards by masking
Other uses for encryption include:	sensitive data (SSN, DOB, etc.).
• Non-repudiation • Digital Rights Management (DRM) • Digital	• Sometimes used to turn production data into testing data
Signature • Tunneling	by masking sensitive data points.
Certificate Revocation:	Black/White List:
•Certificates revoked when:	• The blacklist is an explicit deny.
• They expire.	• The whitelist is an implicit deny.
•• Security of private key is in doubt.	• The blacklist = "If you are on the list, then you are NOT allowed
CRL	in."
• List issued periodically by CA of certificate serial numbers that	• The whitelist = "If you are NOT on the list, then you are NOT
nave been revoked.	allowed in."
Provides reasons for revocation.	Client-based vulnerabilities, Client system should have:
• CRL has a digital signature to prevent spoofing or DoS attacks.	Licensed as running
• List has a short lifetime.	Current antivirus and antimalware
OCSP	• HIDS
<ul> <li>Uses HTTP request to obtain revocation status from CA.</li> </ul>	Strong encryption
• Provides faster confirmation than CRL.	Limited accounts without administrative privileges
Cryptography:	Continuous monitoring
Privacy	Hardened mobile devices
• Authentication	Server-based vulnerabilities, Server system should:
Integrity	Determine how remote access will be established
Non-repudiation	<ul> <li>Check configuration management be performed</li> </ul>
Security Concepts:	Control data flow
Need-to-Know (access only to what's needed to perform	Methods for defeating a switch:

<ul> <li>Provides a way to hide sensitive data</li> </ul>	Logical Security:
Allows for an integrity check of the data by checking it	<ul> <li>Fail Open/Soft (availability is preserved, but data may not be</li> </ul>
against the hashed value	secure)
The hashed value in no way can be used to identify the	• Fail Secure/Closed (data is secure, but availability is not
priginal data	preserved) Physical Security
	• Fail Safe/Open (systems are shut down / entrances unlocked -
	humans are safe)
	Fail Secure/Closed (entrances are locked)
	• Failover is a fault tolerance (redundancy) concept. If you have
	two redundant NICs; a primary and a backup – and the primary
	fails, the backup is used.
	Database Model should provide:
	Transaction persistence
	Fault tolerance/recovery
	• Sharing
	Security controls

<ul> <li>Threats to a DBMS include:</li> <li>Aggregation (combining data to form sensitive information)</li> <li>Bypass attacks (avoiding controls to access information)</li> <li>Compromising database views (modifying/accessing restricted views)</li> <li>Concurrency (processes running at the same time without proper locks)</li> <li>Contamination (corruption)</li> <li>Deadlocking (denying users who access information at the same time)</li> <li>DoS (preventing authorized access)</li> </ul>	<ul> <li>Token Threats:</li> <li>Something you have may be lost, damaged, stolen from the owner or cloned by the Attacker.</li> <li>Something you know may be disclosed to an Attacker. Attacker might guess a password/PIN.</li> <li>Something you are may be replicated.</li> <li>Token Threat Mitigation Strategies:</li> <li>Multiple factors make successful attacks more difficult to accomplish.</li> <li>Physical security mechanisms may be employed to protect a stolen token from dunication</li> </ul>
<ul> <li>Improper modification (accidental/intentional)</li> <li>Inference (deducing restricted information by observation)</li> <li>Interception of data</li> <li>Server access</li> <li>Polymorphism</li> <li>Polyinstantiation</li> <li>TOC/TOU (malicious changing data at a certain time)</li> <li>Web security issues</li> <li>Unauthorized access</li> </ul>	<ul> <li>stolen token from duplication.</li> <li>Imposing password complexity rules may reduce the likelihood of a successful guessing attack.</li> <li>System and network security controls may be employed to prevent an Attacker from gaining access to a system or installing malicious software.</li> <li>Periodic training may be performed to ensure the Subscriber understands when and how to report compromise (or suspicion of compromise) or otherwise recognize patterns of behavior that may signify an Attacker attempting to compromise the token.</li> <li>Out of hand tochniques may be employed to varies proved to</li> </ul>
Aggregation vs. Inference: Inference (understand business, risk analysis, interview owner); by combining multiple reports or source of information, you succeed in guessing or making up new information. Aggregation (understand data and fields); the sum may represent a level of security higher than each of the parts. Be aware of these terms: • Polyinstantiation: Prevents inference attacks • Database Views: Constrained interfaces, restrictive interface • Context-dependent access control: Content dependent controls • Noise and perturbation: Addresses inference attacks • Cell suppression: A technique used against the inference Noise and perturbation: A technique of inserting bogus information in the hopes of misdirecting an attacker or confusing the matter enough that the actual attack will not be fruitful. <b>Tokens - "Synchronous" vs. "Asynchronous":</b> • Synchronous Dynamic Password Tokens Hardware tokens that create synchronous dynamic passwords are time-based and synchronized with an authentication server. They generate a new password periodically, such as every 60 seconds. This does require the token and the server to have accurate time. • Asynchronous Dynamic Password Tokens does not use a clock. Instead, the hardware token generates passwords based on an algorithm and an incrementing counter. When using an incrementing counter, it creates a dynamic one-time password that stays the same until used for authentication. Some tokens create a one-time password when the user enters a PIN provided by the authentication server into the token. <b>Token Usage:</b> • Single-token authentication	<ul> <li>Theft - Use multi-factor tokens which need to be activated through a PIN or biometric.</li> <li>Duplication - Use tokens that are difficult to duplicate, such as hardware cryptographic tokens.</li> <li>Discovery - Use methods in which the responses to prompts cannot be easily discovered.</li> <li>Eavesdropping <ul> <li>Use tokens with dynamic authenticators where knowledge of one authenticator</li> <li>does not assist in deriving a subsequent authenticator.</li> <li>Use tokens that generate authenticators based on a token input value.</li> <li>Establish tokens through a separate channel.</li> </ul> </li> <li>Offline cracking <ul> <li>Use a token with a high entropy token secret</li> <li>Use a token that locks up after a number of repeated failed activation attempts.</li> <li>Phishing or pharming - Use tokens with dynamic authenticators where knowledge of one authenticator.</li> <li>Social engineering - Use tokens with dynamic authenticators where knowledge of one authenticator.</li> <li>Online guessing - Use tokens that generate high entropy authenticators.</li> </ul> </li> </ul>
Types of tokens for e-authentication:         • Memorized Secret Token         • Pre-registered Knowledge Token         • Look-up Secret Token         • Out of Band Token         • Single-factor (SF) One-Time Password (OTP) Device         • Single-factor (SF) Cryptographic Device         • Multi-factor (MF) Software Cryptographic Token         • Multi-factor (MF) One-Time Password (OTP) Device         • Multi-factor (MF) Cryptographic Device	<ul> <li>yet authorized for use</li> <li>The active state: The key may be used to cryptographically protect information</li> <li>The deactivated state: The crypto period of the key is expired, but the key still needs to perform cryptographic operations</li> <li>The destroyed state: The key is destroyed here</li> <li>The compromised state: The key is released or determined by an unauthorized entity</li> <li>The destroyed compromised state: The key is destroyed after a compromise or the compromise is found after the key is destroyed</li> </ul>

Key Management:	• PMO manages the methodologies, standards, overall

• Do your due diligence	remediation
Plan early for an exit	Prudent management of the CSP business
<ul> <li>Design your application to be loosely coupled</li> </ul>	Monitoring, auditing, inspections, maintaining metrics, reports
Maximize portability of your data	Essential characteristics of Cloud:
Consider a multi-cloud strategy	Resource pooling. Multiple customers
<ul> <li>Implement DevOps tools and processes</li> </ul>	<ul> <li>On-demand self-service. Unilateral provisioning</li> </ul>
Note: A poorly crafted contract can lead to vendor lock-in	<ul> <li>Broad network access. Network and client</li> </ul>
	• Rapid elasticity. Speedy provisioning and deprovisioning
	Measured Service. Pay per use

# Cloud Data Life Cycle:

- Create: Creation is the generation of new digital
- Store: Storing is the act committing the digital data
- Use: Data is viewed, processed, or otherwise used
- Share: Information is made accessible to others
- Archive: Data leaves active use and enters long-term storage
- Destroy: Data is permanently destroyed

# Identity as a Service IDaaS:

Identity as a Service (IDaaS) is an authentication infrastructure that is built, hosted and managed by a third-party service provider. IDaaS can be thought of as single sign-on (SSO) for the cloud. This can provide benefits including integration with cloud services and remove overhead for maintenance of traditional on-premise identity systems, but it can also create risk due to the third-party control of identity services and reliance on an offsite identity infrastructure. An IDaaS solution via a cloud provider usually includes the following:

- Single sign-on
- Provisioning
- Password management
- Access governance

# Cloud:

- Anything as a Service (XaaS): The understanding that there is a vast amount of services available across the internet so you don't need to stand up an on-premises solution.
- Cloud app: A cloud application accessed across the internet, not installed locally. Cloud Application Management Platform (CAMP): A specification designed to ease management of applications across public and private cloud platforms.
- Cloud computing: A type of computing that shares computing resources of remote environments to accomplish work, instead of using local servers.
- Cloud database: A database accessible to clients across the internet. Also refers to Database as a Service (DBaaS). These cloud databases use cloud computing to achieve optimization, scaling, high availability, and multitenancy.
- Cloud enablement: Making cloud services available to a client.
- Cloud management: Software and technology used to monitor and operate cloud environments. These tools help ensure cloud resources are working optimally.
- Cloud portability: The ability to move applications and data between different cloud service providers (CSPs) or between public and private cloud environments.
- Cloud provisioning: The deployment of cloud services to meet a need.
- Cloud service provider (CSP): Company providing cloud services to customers.
- Desktop as a Service (DaaS): A virtual desktop infrastructure (VDI), also called a hosted desktop service. Simply a desktop in the cloud you connect to and use with applications installed on it.
- Enterprise application: Applications or software used by large organizations. Generally refers to large-scale applications not suited for small business or individual needs.
- Hybrid cloud storage: A combination of public and private cloud storage. Sensitive data will reside in the private cloud, while other data or applications may reside in the public cloud.

- Infrastructure as a Service (IaaS): A computer infrastructure being delivered as a service. This includes compute, storage, network, and internet access. Simply a fully functional virtual environment on which customers provision virtual hosts.
- Managed service provider (MSP): Managed service providers (MSPs) provide various IT services to customers such as monitoring, patching, help desk, and network operations center.
- Multi-tenant: Having multiple customers using the same public cloud. Data is logically separated by security controls but still runs on the same shared underlying hardware.
- On-demand services: Service model allowing customers to scale their consumed resources without assistance from the provider in real time.
- Platform as a Service (PaaS): A cloud-based platform on which clients deploy their applications. The CSP will manage all underlying infrastructure, including operating system, compute hardware, and network. The customer is only responsible for managing their application code.
- Private cloud: Also known as internal or corporate cloud, this cloud compute platform is protected by the corporate firewall under the control of the IT department, not a CSP. Allows the IT department to control the security of the data and meet regulatory compliance. May be a corporate-owned data center referred to as a corporate cloud or can also be provided by a CSP offering isolated cloud services.
- Public cloud storage: Cloud storage in which the enterprise and storage services provider are separate and the data is stored outside the enterprise data center.
- Software as a Service (SaaS): Cloud-based software offered to clients accessed across the internet, most often as a web-based service. Think web-based applications you log in to and use.
- Vertical cloud computing: The optimization of cloud computing and services for a specific industry. An example would be cloud resources for the entertainment industry, which may have GPUs available to increase compute power for rendering of images and video.

# Cloud API Security Concern:

A cloud API is basically used to integrate applications in order to enhance the cloud experience and provide inter-cloud compatibility. They are broadly classified into two categories: inprocess APIs and remote APIs.

• Ensuring proper security measures to safeguard hypervisor to any sort of security threat.

• Careful assessment of the security practices as implemented by the cloud service providers need to be done before adopting any of them

Proper SLAs between the customer and the CSP, defining the organizations' security requirements that need to be addressed.
APIs in use need to be looked after and screened carefully. In the current scenario, most of the organizations prefer an integration of security techniques with their service models. They should be aware of the security implications associated with the usage of these cloud services. Reliance on weak APIs may jeopardize the security of important organizational data.

<ul> <li>Provide Secure Password Management:</li> <li>Send non-temporary passwords only over an encrypted connection or as encrypted data (such as in an encrypted email). Temporary passwords associated with email resets may be an exception.</li> <li>Enforce password complexity requirements established by policy or regulation.</li> <li>Prevent password re-use.</li> <li>Hide password entry on the user's screen by default.</li> <li>Disable accounts after an established number of failed login attempts to prevent brute force attacks.</li> <li>Require the same level of security controls for password reset and changing operations as you require for account creation and authentication.</li> <li>Support sufficiently random answers for password reset questions.</li> <li>If using email-based resets, only send email to a pre-registered address with a temporary link/password.</li> <li>Provide a short expiration time for temporary passwords and links.</li> <li>Require temporary passwords to be changed on the next use.</li> <li>Notify users when their password has been reset (outside of the application, using their preregistered email address, for example).</li> <li>Enforce password changes based on requirements established in</li> </ul>	<ul> <li>Do not store passwords, connection strings, or other sensitive information in cleartext on the client side.</li> <li>Disable auto-complete features on forms expected to contain sensitive information, including authentication.</li> <li>Disable client-side caching on pages containing sensitive information.</li> <li>Establish and follow a policy and process for managing encryption keys.</li> <li>Cloud services are broken down into three capabilities:         <ul> <li>Application capability: The cloud service customer uses the cloud service provider's applications.</li> <li>Infrastructure capability: The cloud service customer can provision and use processing, storage, or networking resources.</li> <li>Platform capability: The cloud service customer can deploy, manage, and run their own applications using one or more programming languages and one or more execution environments supported by the CSP.</li> </ul> </li> <li>Cloud deployment model:         <ul> <li>Risk appetite</li> <li>Cost</li> <li>Compliance and regulatory requirements</li> </ul> </li> </ul>
<ul><li>policies and regulations.</li><li>Change all default passwords and user IDs provided with the</li></ul>	<ul> <li>Compliance and regulatory requirements</li> <li>Legal obligations</li> <li>Business strategy</li> </ul>
<ul> <li>development platform or services.</li> <li>Protect Data in Transit and at Rest: <ul> <li>Minimize the need for encryption by eliminating collection and storage of sensitive data as much as possible.</li> </ul> </li> </ul>	Cloud Computing Roles Cloud customer: An individual or organization that uses cloud-
<ul> <li>Base your selection of cryptographic and key management algorithms to use on the objectives of the application, and use the most appropriate algorithm suite for the objectives. (Don't default to simply using libraries that are already available to you.)</li> <li>Implement all cryptographic functions on a trusted system, such as a server.</li> <li>Generate random numbers, random file names, random GUIDs, and random strings using your encryption library's approved random number generator.</li> </ul>	based services. Cloud service auditor: A third party that verifies CSPs are meeting service-level agreements (SLAs). Cloud service brokerage (CSB): Organization that looks to add value to cloud services through relationships with multiple CSPs. They are used to help customers identify the best cloud solution for them. CSBs sometimes resell cloud services. Cloud service provider: Company providing cloud services to customers. Cloud service partner: Includes other roles, such as cloud service auditor and cloud service broker.
<ul> <li>Use encryption libraries that comply with FIPS 140-2 or an equivalent standard.</li> <li>Ensure that cryptographic modules fail securely.</li> <li>Utilize a single standard TLS implementation that is configured appropriately.</li> <li>Use encryption (such as provided by TLS) to protect all sensitive information (such as credentials) sent over the network.</li> </ul>	CapEx vs. OpEx: • CapEx: Capital expenditure (CapEx) is an upfront investment of a sum of money into a business requirement, such as a building, server farm, network environment, or network operations center (NOC)
<ul> <li>Pre-encrypt files you must transmit over unencrypted channels.</li> <li>When encrypted channels fail, do not fall back to an unsecure connection, unless you encrypt data before sending.</li> <li>Make sure TLS certificates are valid and have the correct domain name, not expired, and installed with intermediate certificates when required.</li> <li>Specify character encodings for all connections.</li> <li>Protect all sensitive data stored on the server (include caches and temporary copies) from unauthorized access.</li> <li>Remove any sensitive data from the system as soon as it is no longer required.</li> <li>Purge temporary working files as soon as they are no longer needed.</li> <li>Use strong encryption algorithms.</li> <li>Protect server-side source-code from being downloaded by a user.</li> </ul>	<ul> <li>OpEx: An OpEx is an operational expenditure where you are paying for a service on a schedule. An example of this would be a building lease or utilities. However, this applies to services as well, such cloud services or hosting services</li> <li>CapEx vs. OpEx: Businesses may not have large amounts of capital at their disposal, so instead of building out an on-premises compute solution that could cost large amounts of money, they may instead look into a cloud solution. If the business stands up their compute needs in the cloud, they are paying month to month on only what is needed. Whereas, if they built out their on-premises solution, they would have to invest large amounts of capital upfront and then pay for ongoing costs, such as electricity, warranties, support contracts, and eventually replacement.</li> </ul>

<ul> <li>Cloud-Specific Risks:</li> <li>Management plane breach: Most important risk because this would give the attacker access to the entire infrastructure.</li> <li>Resource exhaustion: Oversubscription by the CSP may result in a lack of resources for your cloud services, which may cause an outage</li> <li>Isolation control failure: When one tenant is able to access another tenant's resources or affect another tenant's resources.</li> <li>Insecure or incomplete data deletion: Be sure to use crypto shredding.</li> <li>Control conflict risk: Implementing excessive controls can cause a lack of visibility.</li> <li>Software-related risk: Software is prone to vulnerabilities and must be kept up to date.</li> <li>Man-in-the-middle attacks: Cloud solutions increase the risk of man-in-the-middle attacks.</li> </ul>	Benefits of Identity as a Service IDaaS: • SSO authentication • Federation • Granular authorization controls • Administration • Integration with internal directory services • Integration with external services SSO Technologies: • Kerberos • SESAME • LDAP • Microsoft Active Directory OAuth Flow: • Ask for a request token • Get Temporary credentials • Exchange for an access token Virtualization Risks: • VM Sprawl • Sensitive Data within a VM • Security of Offline and Dormant VMs
Multi-cloud: MC is where a business wants to spread their TI across multiple clouds, public and private to get the required levels of privacy, security and resilience, avoiding a single vendor lock-in. However, adopting a multi-cloud approach introduces many challenges around the management and interoperability of applications and services.	<ul> <li>Security of Pre-Configured (Golden Image) VM / Active VMs</li> <li>Lack of Visibility Into and Controls Over Virtual Networks</li> <li>Resource Exhaustion</li> <li>Hypervisor Security</li> <li>Unauthorized Access to Hypervisor</li> <li>Account or Service Hijacking Through the Self-Service Portal</li> <li>The workload of Different Trust Levels Located on the Same Server</li> <li>Risk Due to Cloud Service Provider API</li> </ul> <b>Prevent Vulnerabilities in Virtual Machine Infrastructure:</b> <ul> <li>Make sure that a patch management system is in place.</li> <li>Provide the minimum access needed in virtual machines and virtual networks.</li> <li>Log and review user and system activities in the virtual environment.</li> <li>Pay special attention to how you configure virtual networking devices.</li> <li>Consistently capture snapshots or the state of the virtual environment.</li> <li>Carefully monitor the number of virtual machines to avoid VM sprawl.</li> <li>Protect against VM escape</li> </ul>

#### Prevent Vulnerabilities in Virtual Machine Infrastructure

Make sure that a patch management system is in place to ensure that all relevant patches are installed. This is especially important for any patches released that apply to the virtualization software itself. Also, carefully determine when and if general operating system patches should also be installed on the host and guests.
Provide the minimum access needed in virtual machines and virtual networks to meet requirements. This will limit potential

damage if security is breached. Monitor access to all environments on a regular basis to prevent unauthorized access.

• Log and review user and system activities in the virtual environment to check for irregular activity and any possible security breaches.

• Pay special attention to how you configure virtual networking devices, enabling network connectivity between systems only when necessary. Note that the security capabilities of virtual networking appliances may not be exactly the same as a physical device. For example, virtual switches in certain modes may fail to isolate traffic between host and guest or guest and guest in a virtual infrastructure.

• Consistently capture snapshots, or the state of the virtual environment at a certain point in time, to provide a quick and easy way to recover the entire environment should it be compromised. Carefully monitor the number of virtual machines to avoid VM sprawl, which occurs when the number of virtual machines exceeds the organization's ability to control or manage all of those virtual machines. A compromised VM could easily slip by your notice if you're dealing with VM sprawl. One of the best ways to avoid VM sprawl is to use a VM lifecycle management (VMLM) solution. VMLM solutions provide you with a centralized dashboard for maintaining and monitoring all of the virtual environments in your organization. Protect against VM escape, which occurs when an attacker executes code in a VM that allows an application running on the VM to "escape" the virtual environment and interact directly with the hypervisor. The attacker may be able to access the underlying host operating systems and thereby access all other VMs running on that host machine. The best way to protect against VM escape is to ensure that your virtualization software is kept up-to-date. You can also attempt to limit the resource sharing functionality between host and guest.

#### **Provide Secure Session Management:**

• Create session IDs only on trusted systems, such as a server.

• In session IDs, do not include any information that is descriptive of the application environment or any user information that would be useful to an attacker performing reconnaissance.

• Make session IDs random and long enough (e.g., 20 bytes or longer) to prevent guesswork or brute force attacks.

• Use the session management controls provided by the server or framework that use algorithms that produce sufficiently random session IDs.

• Set a restrictive domain and path for cookies containing authenticated session IDs.

• Fully terminate the associated session or connection upon logout.

• Provide the ability to log out from all pages protected by authorization.

• Establish a session inactivity timeout that is as short as possible to support business functional requirements.

• Enforce periodic session terminations, even when the session is active, providing warnings to the user as needed.

• Close any sessions established before login and establish a new session after successful login.

• Generate a new session ID and deactivate the old one periodically:

Upon reauthentication

cookie's value.

• If the connection security changes from HTTP to HTTPS

• Locate session IDs only in the HTTP cookie header, and do not expose them in URLs (e.g., GET parameters), error messages, or logs.

• Within an application, consistently utilize HTTPS rather than switching between HTTP and HTTPS.

• Supplement standard session management for sensitive or critical operations such as account management—for example, using per-session strong random tokens or parameters.

• Set the secure attribute for cookies transmitted over a TLS connection.

Protect session data on the server from unauthorized access by implementing appropriate access controls on the server.
Apply the HttpOnly attribute to cookies, unless you specifically require client-side scripts within your application to read or set a

Various versions have been developed in wireless networking hardware, including 802.11a 802.11b, 802.11g, 802.11n, 802.11ac as described in the table below:</li> <li>802.11 2 Mbps 2.4 GHz</li> <li>802.11a 54 Mbps 5 GHz</li> <li>802.11a 100+ Mbps 2.4 GHz</li> <li>802.11a 200+ Mbps 2.4 GHz</li> <li>802.11a 1 Gbps 5 GHz</li> <li>902.11a 1 Gbps 5 GHz</li> <li>903.11a 1 Gbps 5 GHz</li> <li>904.11 (Gbps 1 Gbps 1 G</li></ul>	Administrative Simplification Rules. Important HITECH Features: • Expansion of HIPAA security standards to "business associates" that perform activities involving the use or disclosure of individually identifiable health information. • Increased civil penalties for "willful neglect." • Data-breach notification requirements for unauthorized uses and disclosures of "unsecured PHI." • Stronger individual rights to access electronic medical records and restrict the disclosure of certain information. • New limitations on the sale of protected health information, as well as marketing and fundraising communications. <b>EU Data Protection Directive Features:</b> • Notice: Data subjects should be given notice when their data are being collected. • Purpose: Data should only be used for the purpose stated. • Consent: Data should not be disclosed without the subject's consent. • Security: Collected data should be kept secure from any potential abuses. • Disclosure: Data subjects should be informed as to who is collecting their data. • Accountability: Data subjects should be allowed to access their data and make corrections to any inaccurate data. • Accountability: Data subjects should have an available method to hold data collectors accountable for following these six principles above. <b>COBIT :</b> • Principle 1: Meeting Stakeholder Needs • Principle 2: Covering the Enterprise End to End • Principle 3: Applying a Single, Integrated Framework • Principle 4: Enabling a Holistic Approach • Principle 4: Enabling a Holistic Approach • Principle 5: Separating Governance from Management <b>ITIL Benefits:</b> • Increased user and customer satisfaction with IT services. • Improved service availability, directly leading to increased business profits and revenue. • Financial savings from reduced rework, lost time, improved resource management and usage. • Improved time to market for new products and services. • Improved time to market for new products and services. • Improved decision-making and optimized
<ul> <li>Electronic Transaction and Code Sets Standards: Requires the same health care transactions, code sets, and identifiers.</li> <li>Privacy Rule: Provides federal protections for personal health information held by covered entities and gives patients an array of rights with respect to that information.</li> </ul>	<ul> <li>Security safeguards principle</li> <li>The openness principle</li> </ul>

## Information Security:

The key goal of information security is to reduce adverse impacts on the organization to an acceptable level. Following are some other security management framework & methodologies for security professionals, which includes development standards, security architect, security controls, governance methods & management process:

•ISO/IEC 17799:2005 Information technology - Security techniques - Code of practice for information security management • ISO/IEC 27000 Series family of Information Security Management Systems

- ISO/IEC 27001 Information Security Management
- ISO/IEC 27002 Code of practice for information security controls
- Common Criteria (CC) or ISO/IEC 15408
- Information Technology Infrastructure Library (ITIL)
- Zachman framework
- TOGAF
- DoDAF
- MODAF
- COBIT

# The structure of the TOGAF documentation:

• PART I: (Introduction)- This part provides a high-level introduction to the key concepts of enterprise architecture and, in particular, the TOGAF approach. It contains the definitions of terms used throughout TOGAF and release notes detailing the changes between this version and the previous version of TOGAF.

• PART II: (Architecture Development Method) - This part is the core of TOGAF. It describes the TOGAF Architecture Development Method (ADM), a step-by-step approach to developing an enterprise architecture.

• PART III: (ADM Guidelines and Techniques) - This part contains a collection of guidelines and techniques available for use in applying TOGAF and the TOGAF ADM.

• PART IV: (Architecture Contenf Framework) - This part describes the TOGAF content framework, including a structured meta-model for architectural artifacts,. The use of re-usable architecture, building blocks, and an overview of typical architecture deliverables.

• PART V: (Enterprise Continuum & Tools) - This part discusses appropriate taxonomies and tools to, categorize and store the outputs of architecture activity within an enterprise.

• PART VI: (TOGAF Reference Models) - This part provides a selection of architectural reference models, which includes the TOGAF Foundation Architecture, and the Integrated Information Infrastructure Reference Model (III-RM).

• PART VII: (Architecture Capability Framework) - This part discusses the organization, processes, skills, roles, and responsibilities required to establish and operate an architecture function within an enterprise.

### SABSA:

SABSA is comprised of a series of integrated frameworks, models, methods, and processes used independently, or as a holistic integrated enterprise solution, including:

- Business Requirements Engineering Framework (known as Attributes Profiling)
- Risk and Opportunity Management Framework
- Policy Architecture Framework
- Security Services-Oriented Architecture Framework
- Governance Framework
- Security Domain Framework
- Through-life Security Service Management & Performance Management Framework

#### The GDPR defines three relevant entities:

• Data subject The individual to whom the data pertains

- Data controller Any organization that collects data on EU residents
- Data processor Any organization that processes data for a data controller

# GDPR:

GDPR requires that organizations adhere to the rules of Privacy by Design. Privacy by Design is an approach to software development that takes privacy into account throughout every phase of development. The underlying premise of Privacy by Design is not simply protecting data, but as much as possible designing systems so data doesn't need protection—for example, minimizing data collected in the first place.

## Identify Personal Data as Defined by GDPR:

GDPR defines personal data as "any information relating to an identified or identifiable natural person (data subject). An identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier" such as: • A name

- An identification number
- Location data
- An online identifier

• One or more factors specific to the data subject's physical, physiological, genetic, mental, economic, cultural, or social identity

The GDPR set of protected types of privacy data:	Meet PCI DSS Requirements:

•• Account Monitoring and Control	protections such as blocking certain traffic patterns to prevent
Organizational CIS Controls	vulnerabilities from being exploited.
•• Implement a Security Awareness and Training Program	Protect Privacy:
Application Software Security	To ensure that personal information and privacy are protected:
<ul> <li>Incident Response and Management</li> </ul>	Minimize data collection.
<ul> <li>Penetration Tests and Red Team Exercises</li> </ul>	• Consult with data scientists and legal and compliance teams to
	determine risk of data collection and storage.
	• Provide end users the option to specify what data will be
	collected.
	Anonymize collected data.
	Use encryption to protect all collected personal data at rest and
	in transit.
	• Ensure that collected personal information is accessible only by
	authorized users.
	Ensure that a data retention policy is in place.

### Protect Sensitive Information:

Some information may require special care and handling in your application to protect users. Identify any information that is sensitive, and apply appropriate controls to ensure it remains private. A good place to start is to always consider all personally identifiable information (PII) sensitive, as it can be used to establish a person's identity and might be used to cause them substantial harm, embarrassment, inconvenience, or unfairness. Refer to privacy guidelines for your country, municipality, or organization for specific lists of PII you may be legally required to protect. A typical list is provided here.

organization for specific lists of PII you may be legally required to	• Provide release notes with software updates to clearly and simply
protect. A typical list is provided here.	explain how terms and conditions change over time.
• User name	• Track which users have consented to the terms and conditions,
Email address	including the version if terms and conditions have changed over
Home address	time.
Phone number	• Implement a Do Not Track feature on the server side, so users
<ul> <li>Social Security number (even if it's just the last 4 digits)</li> </ul>	can disable tracking, and provide an opt-out capability for users.
<ul> <li>Driver's license or state ID#</li> </ul>	• Provide users with a list of all tracking mechanisms used in the
Passport number	software, explaining how and by whom the information is used.
<ul> <li>Alien registration number</li> </ul>	• Inform users (through a clear and well-written terms and
<ul> <li>Financial account number</li> </ul>	conditions page, for example) how data is processed, including
Biometric identifiers	collection, storage, processing, and deletion.
<ul> <li>Citizenship or immigration status</li> </ul>	Do Not Collect Non-Essential Data:
<ul> <li>Medical information</li> </ul>	When data that is not needed to meet requirements is collected, it
<ul> <li>Ethnic or religious association</li> </ul>	needlessly puts privacy at risk. To avoid this defect:
<ul> <li>Sexual orientation</li> </ul>	• Do not collect descriptive, demographic, or any other user-
Account passwords	related data that are not needed for the purposes of the system.
Date of birth	• Enable users to opt out of providing additional data to improve
Criminal history	the service.
